

ENTERPRISE IT CLARIFICATION

# Answer Matrix — Kynvera FM operations platform

Not a generic chatbot and not a replacement for ERP or Microsoft 365. Records live in your PostgreSQL. The assistant reads only what the signed-in user may see. Writes are proposals until a human confirms.

Q1-9 · BOUNDARY, GROUNDING, SCALE

| # | Question                                                           | Answer                                                                                                                                                                                                                              |
|---|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 | Does operational / HR / commercial data leave? Is the LLM on-prem? | Records stay in your DB and approved stores. LLM is provider-agnostic: approved cloud, your compatible endpoint, or off. Cloud sends only prompt + snippets for that turn. No bulk dump. No fine-tune of your data at the provider. |
| 2 | Complete architecture, integrations, data flow?                    | Yes — Architecture Deck: components, trust boundary, flows A–F.                                                                                                                                                                     |
| 3 | How are critical fields / SLA terms preserved?                     | Typed DB rows and JSON form_data with workflow history — not naive chat chunking. Assistant facts come from live SQL scoped to the user.                                                                                            |
| 4 | How do you prevent hallucinated costs, SLA, assignments, policy?   | Grounded tools + confirm-before-write + labelled estimates. Counts and IDs from SQL. Missing sources → “I don’t have that.” Triage never auto-applies. Markup is a supervisor field.                                                |
| 5 | How does it scale? Data loss on large packs?                       | Web, Postgres, Redis, Cloudinary, report workers scale independently. Email intake is logged even on failure. Persistent disk required for generated reports.                                                                       |
| 6 | Hardware: CPU, RAM, GPU?                                           | 2–4 vCPU, 8 GB min / 16 GB rec, 100 GB+ SSD, Ubuntu, Postgres, Redis. GPU unused.                                                                                                                                                   |
| 7 | Accuracy rates? Validation before users see output?                | No single headline number. Trust is by construction: live SQL, RAG over approved knowledge, Confirm on writes, labelled estimates.                                                                                                  |
| 8 | Inbound ticket email? Browser automation?                          | Mailjet Parse → secret webhook → draft ticket. No tender-portal browser bot. Wrong secret returns 404.                                                                                                                              |
| 9 | What is automated vs human?                                        | Automation processes and drafts. People approve, assign, sign, close, convert email drafts, and set markup.                                                                                                                         |

Q9 — process vs sign-off

Q10–18 · INTEGRATIONS, ACCESS, OPERATIONS

| #  | Question                                          | Answer                                                                                                                                                                 |
|----|---------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10 | Microsoft 365, Google Drive, email, WhatsApp?     | Email (Mailjet/Brevo/SMTP) and optional Google Drive are native. No Microsoft Graph tenant grant. WhatsApp is not a product channel; field photos go app → Cloudinary. |
| 11 | Cloudinary / email / Drive — sensitive site data? | Each is an explicit payload. Drive uses drive.file only (Kynvera Files root). Keep highly sensitive HR/commercial files in-app / DocHub unless policy permits Drive.   |
| 12 | CAFM / ERP (MRI, Dynamics, SAP)?                  | MMR already ingests CAFM-style Excel/HTML. Generic authenticated API + webhooks. Named ERP/BMS connectors after discovery.                                             |
| 13 | Separate VPS for heavy work?                      | No public VPS. PDF/Excel/MMR run as jobs on the app host or a worker inside the same boundary.                                                                         |
| 14 | Concurrent users / tickets?                       | Tens of concurrent interactive users on the reference VM. Re-size for heavy PDF/Excel. Confirm in a scoped pilot.                                                      |
| 15 | Restrict by module, project, ticket, document?    | Yes. Role + designation + access_ * + ticket ACL + DocHub list. Retrieval filters so the assistant cannot see what the user cannot.                                    |
| 16 | Vulnerabilities, pen tests, certifications?       | Secure SDLC, headers, rate limits, non-root container. No default third-party pen-test or ISO pack. VAPT can be your go-live gate.                                     |
| 17 | Support after deployment?                         | Internal product, operated by Injaaz. Warranty/handover as contracted. Stack is runnable independently.                                                                |
| 18 | If Microsoft 365, Cloudinary, or LLM is down?     | Core login, forms, tickets run if app + Postgres are up. LLM/mail/Drive/Cloudinary degrade as documented.                                                              |

Source: production validator + .env.example. Postgres and Cloudinary are required in production; LLM, Drive, inbound mail, Redis, and geocode are optional.

Q19–27 · BACKUP, OWNERSHIP, ACCESS

| #  | Question                                                 | Answer                                                                                                                                          | Backup ownership     |
|----|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|
| 19 | Business continuity / DR?                                | Postgres backups, versioned app deploy, GENERATED_DIR on persistent disk, documented restore. Optional provider PITR / OCI snapshots.           | You own Postgres1    |
| 20 | Who owns AI “memory” backups?                            | You do. FAQs, admin knowledge, pending actions, triage logs, audit are in PostgreSQL. No fine-tuned copy at the model provider.                 | You own disk1        |
| 21 | App server fails — restore trained state?                | Stateless app + restore Postgres (+ disk + secrets). Agent logic is versioned code, not model weights.                                          | Cloudinary media1    |
| 22 | Standard backup routines?                                | Follow your IT standard: pg_dump / snapshots; snapshot GENERATED_DIR; Cloudinary for media; secrets never in git.                               | Git + secrets store1 |
| 23 | End-to-end bid-to-finance, or operations + integrations? | FM operations backbone. Complements ERP/finance/CAFM.                                                                                           |                      |
| 24 | Global Administrator on Microsoft 365?                   | Never. No Graph. Optional Drive is user-consented OAuth (drive.file + email/openid). In-app admin is our RBAC role.                             |                      |
| 25 | What does the assistant touch?                           | Only listed tools, as the signed-in user. Writes: propose ticket or leave draft. No approve, close, send mail, or Drive.                        |                      |
| 26 | How does it know what a user may access?                 | Kynvera user record: role, designation, access_*, ticket roster, DocHub row. JWT identity is user id.                                           |                      |
| 27 | Restrict pricing / commercial data?                      | Yes. Markup, selling price, chargeable flags are supervisor fields. MMR needs access_report_generation. Assistant has no commercial write tool. |                      |

Use with Architecture Deck (trust boundary) and Agent Connectivity (tools, OAuth, ports). Confirm LLM mode, Cloudinary, mail, and whether Google Drive is in scope before go-live.
